Example: A Java class can have a main method that you can start from the command line or GUI. The main method then uses the appropriate constructor. See Java Tutorials for more details. The main method is equivalent to having a class with a public static void main(String[] args) method. If the program is run using the java command, the main method is automatically called. If the program is run using a Java GUI, the user must choose to "Run" the program. When the program is run using a Java GUI, the main method is automatically called, and no "Run" action is required. To run a program from the command line, use the java command, as follows: Example: If you want to invoke your main method from the command line, you can do so using the -classname option, as follows: Example: Note that in your main method you must invoke one of the constructors for the class, which you can do using the super keyword. See Java Tutorials for more details. You can change the main method's behavior using the java command-line option -X, which allows you to specify a list of options. For more information, see Java Tutorials. Example: The JVM creates its own window and runs your program in it. If you don't want that, you can use the -nopan option. You can also use the -jar option to run a single main class. Example: The -jar option allows you to create self-contained JAR files. Example: In your main method, you can read from the command line using java.util.Scanner. Example: The java.io.BufferedReader class allows you to read from standard input. Example: If you want to write output to the standard output, you can do so using System.out. Example: If you want to write output to the standard error output, you can do so using System.err. Example: This section describes the syntax and usage of the files generated by the Java compiler. Each Java source file is translated into one or more class files. A class file contains information about the class and its components. The class file is a binary representation of the source code. To run the Java compiler, you can use the javac command. You can invoke the javac command from the command line, or from the IDE (although you cannot change the default location of the class files generated by the compiler, which is typically /home/user/javac). Example: When you compile using the javac command, you can pass it the options. These options allow you to control the behavior of the compiler. Example:
